1 Problem presentation

Private Set Intersection (PSI) is a cryptographic technique that allows two parties to compute the intersection of their datasets without revealing nothing more than the intersection result. Protocols of Private Set Intersection have a great importance and use in many fields because of their property of saving confidentiality of data. The cases where such a protocol should be used is whenever one or both parties have to discover information about the intersection of their sets which contain sensitive and private data.

To represent the problem in a more accurate way, we can consider Bob and Alice with two sets of data: $X = \{x_1, x_2, ..., x_n\}$ - Bob's set and $Y = \{y_1, y_2, ..., y_n\}$ - Alice's set.

There are various variants of PSI protocols where both Bob and Alice can compute the intersection of X and Y or only one of them can discover the intersection, in such cases in literature we can find the entities as sender and receiver (just the receiver will gain information). Hence, the problem can be represented not just in a unique way:

Input: X and Y, Bob and Alice sets

Output: $X \cap Y$ for both Bob and Alice

Input: X and Y, Bob is the SENDER

and Alice is the **RECEIVER**

Output: Alice: $X \cap Y$ Bob: \emptyset

2 State of the art

In the last several years, protocols of Private Set Intersection have been vastly studied and many implementations with great results were given. When we look at the efficiency of a PSI protocol we have to consider two major aspects: the computation cost and the communication cost.

The first one is the necessary computing time to run the protocol and as we optimise it we can limit the computational resources. The computationally efficient protocols are based on Oblivious Transfer (OT), a cryptographic hash function, symmetric-key cryptographic operations and bitwise operations, [1], [2], [3] presents various OT implementations.

The second aspect refers to the amount of communication in the protocol and due to limited network bandwidth minimizing the communication cost becomes a critical side of efficiency. Combining these two aspects, computation and communication, a single metric can be computed: the total running time of the protocol, which includes both computation time and communication time. Obviously, this time can vary depending on the network settings so different protocols can reach a better time in different settings.

A great balance between computation time and communication time was reached in [4] by Pinkas. A variant of oblivious transfer extension that they call sparse OT was used. It relies heavily on manipulating high-degree polynomials over large finite fields.

[5] which is also our base reference in the proposed project, introduces the question if [4] achieves the best balance between computation cost and communication cost. The authors, Melissa Chase and Peihan Miao, come with a negative answer proposing a new PSI protocol which is a new multi-point oblivious pseudorandom function(OPRF) protocol based on oblivious transfer extension. This new protocol achieves a better balance between computation and communication which is based only on oblivious transfer, hashing, symmetric-key and bitwise operations.

3 Implementation

In this section, we will present our implementation for the PSI, followed by pictures of the application. Our implementation is based on a client-server architecture, where a single client can run the protocol with the server at any given time.

On the server side, before the server can be started the user must choose to what port and address the server will be bound and choose a file, csv or xlsx, from which he will be able to choose one of the columns present in the file to use the data from that column as data in the protocol. Once the server is started, it will wait for any incoming connection from a client. When a client connects, his address and port will be shown in the server interface, a example being illustrated in Figure 1.

Figure 1: Server interface

On the client side, the user will have to go trough a connection tab, shown in Figure 2, where he must choose to what port and address the client will be bound and to offer the address and the port to the server they want to connect. Once the connection is validated, the user will be sent to a second tab, where he will choose what parameters he wants to use, similarly to the server choose a file and a column as seen in Figure 3. The second tab also has a big text browser where the results of the PSI will be showed, as seen in Figure 6.

Figure 2: Connection interface

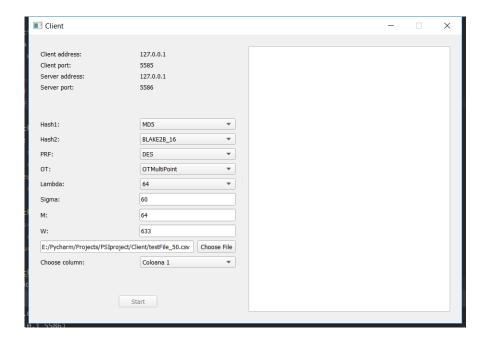

Figure 3: Initial client interface

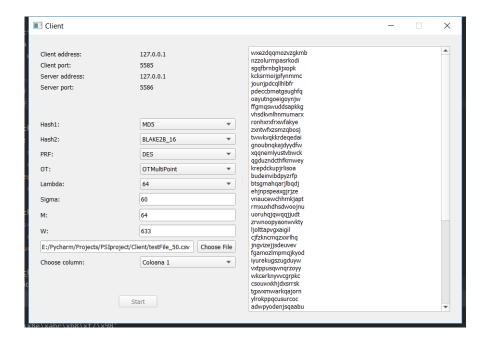

Figure 4: Client interface after executing the protocol

As we can see in the Figures 5 and 6, our application encapsulates the main algorithm service. The focus was on the nucleus algorithm and also on the whole application. The entire application was implemented in Python. For the application, we used PyQt5 for GUI, and for the whole communication service, we used the library socket from Python. The communication service is used for initiating connection, exchanging RSA keys, exchanging AES key/IV encrypted a priori with corresponding RSA keys, and for all protocol operations.

We incorporated some elements of advanced software engineering techniques, including aspects implemented in *aspectlib*. For example, we implemented with aspects an extension which allows to encrypt/decrypt the content transmitted through CommunicationService. We choose to implement this feature using aspects because it's an extra feature which can be discarded anytime in algorithm without much refactoring.

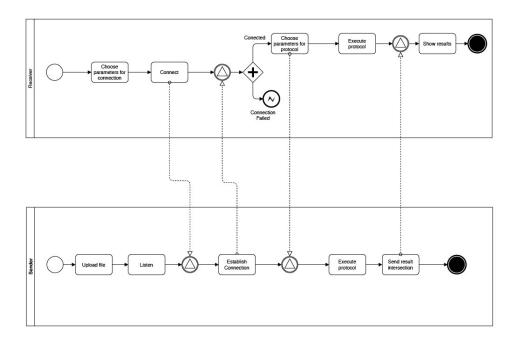

Figure 5: Diagram of the application

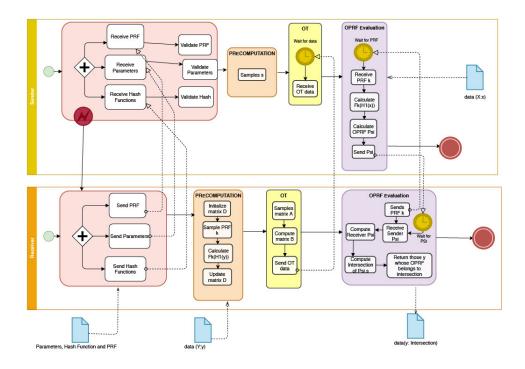

Figure 6: Nucleus algorithm BPMN diagram

A significant role in the entire protocol is played by the primitives that we can see as the bricks on which the entire protocol is built.

The smallest primitives we used are hash functions: BLAKE2, MD5, SHA1, SHA256, SHA384, SHA512, SHA3_256, SHA3_384, SHA3_512 and ciphers: AES, DES and DES3 that used in different modes such as CTR, ECB or CBC play different roles: any cipher in the CTR mode is considered to be a psudorandom generator (we note it with PRG), while using it in the ECB mode represents a pseudorandom function (we note it with G). The CBC mode is considered to be a generic mode.

All of these small primitives were implemented using Pycryptodome library available in Python 3.

In the following, we present the scheme for the F function (applied on a key k and input $x = x_0 || x_1$) used in our implementation, which was taken from the aforementioned article.

$$F_k(x) = G_{k_1}(G_{k_0}(x_0) \oplus x_1) ||G_{k_2}(G_{k_0}(x_0) \oplus x_1)|| \dots ||G_{k_t}(G_{k_0}(x_0) \oplus x_1)|| \dots |$$

where
$$G: \{0,1\}^{\lambda} \times \{0,1\}^{\lambda} \rightarrow \{0,1\}^{\lambda}$$
,

$$PRG: \{0,1\}^{\lambda} \rightarrow \{0,1\}^{(t+1) \cdot \lambda}, \: t = \left\lceil \frac{w \cdot log(m)}{\lambda} \right\rceil$$

and
$$k_0||k_1||\dots||k_t \leftarrow PRG(k)$$
.

4 Results, Measurements and Statistics

In this section, we will present the measurements we did on our implemented protocol in Python and with our desired architecture. Keep in mind that the results measured are only for algorithm, included the security features (AES encryption of the channel). Our scope is to prove statistically the pseudoliniarity of the protocol, and to get the best optimal combination of primitives.

First of all, we would like to test that our protocol is linear. So, we have some data scaling reports for the following constant hyperparameters: lambda = 128, m = 256, w = 633, hash1 = SHA256, hash2 = MD5, prf = AES, otVariant = 1:

Table 1	:	Measurements	for	n =	len	(data)	=	512
---------	---	--------------	-----	-----	-----	--------	---	-----

n	Time
8	16.907427072525024

32768	1212.2749524116516
65536	2477.1293470859528

Next, we are going to present the main statistics of this article, in which we are going to show our results in combining different primitive types as follows. Our results are calculated or the following hyperparameters set: w = 100, m = len(data). In the first column, we have the first type of hash, needed in the algorithm. In the second one, we have the second type of hashing. In the third column, we have the pseudo random function which is the basement for the pseudo random algorithm constructed in the algorithm. Each table is associated with a desired number of elements n for each entity (Sender/Receiver). In the next two columns, we have the results (in seconds) of running time of the algorithm (on the Receiver) for both approaches of Oblivious Transfers implemented in algorithm. For each table, we have graded the results with different colors, as following: the green color is associated with the best time, the cyan for the next 9 ones, the yellow for the following 20 values, the orange for the next 20 recordings, and red for the worst 14 values.

Table 2: Measurements for n = len(data) = 512

5 Comparison with other solutions

Our goal so far has been to implement a version of the Private set intersection protocol that is robust and efficient enough. The main reference, for this purpose, is *Private Set Intersection in the Internet Setting From Lightweight Oblivious PRF* published by Melissa Chase and Peihan Miao and presented at *Advances in cryptology – CRYPTO 2020*. We decided that this approach is the most appropriate choice because it is based only on oblivious transfer, hasing, symmetric-key and bitwise operations, so it is facil to understand and implement, it was published in 2020, hence it belongs to actual interest and, summarizing the results contained in the article, it achieves a better balance between computation and communication than all the other existent PSI protocols. It is also mentioned in the article that this protocol is the fastest in networks with moderate bandhwidth and, in terms of monetary cost, it compares favourably when running it on a cloud computing service. Underlying the PSI protocol described in the reference, is a new lightweight multi-point pseudorandom function (OPRF) protocol based on oblivious transfer (OT) extension which can also be found in the reference.

We present Table 6 for a better visualization of the differences between our algorithm and that of the authors of the article.

able 6: Comparisons between our version and the 2020 version of Chase and M						
Compared element	Our implementation	Chase and Miao's version				
Programming language	Python 3	C++				
PRF	AES, DES, DES3	AES				
Hash functions	BLAKE2, MD5, SHA1, SHA256, SHA384, SHA512, SHA3_256, SHA3_384, SHA3_512	BLAKE2				
OPRF	multi-point oblivious pesudoran- dom function but with the pos- ibility to use the existing imple- mentation from <i>oblivious</i> library	multi-point oblivi- ous pesudorandom function				
ОТ	extended version of OT but with the posibility to use the exist- ing implementation from <i>oblivi</i> -	extended version of OT				

Table 6: Comparisons between our version and the 2020 version of Chase and Miao

6 Future work

Our future work plan would consist, primarily, in developing a multi-threaded implementation for the communication protocol that allows connecting several clients to the server at the same time.

Furthermore, we can expand the current version of the implementation by finding more cryptographic primitives. For instance, we could develop another version of the F function or use the implementations for OPRF and OT from the library provided by Python3, named oblivious. Another example would be to find other hash functions and to build different pseudorandom functions and generators.

On the other hand, another direction of development we thought of, would be to try implementing the entire protocol in the C + + programming language in order to gain more efficiency.

Finally, we might try a direction which implies a Map-Reduce approach, on multi-nodes distributed system (we would chunk the sender data in multiple nodes to apply the Map-Reduce paradigm). We would like to explore here some different perspectives about optimization, with applicability in Big Data.

7 Conclusions

In conclusion, we succeeded to port the C/C++ variant of the protocol, proposed by the authors of the main article, on the Python in a conventional way. Keeping in mind the language used and the conventional way of implementing the OT, we remark that the obtained statistics are satisfactory. If we are looking into **Section 4: Results, Measurements and Statistics**, at all tables, we conclude that the combinations with Hash1 in {SHA256, SHA3_256, BLAKE2B_32} with PRF construction based on AES, are the most efficient ways of building our algorithm.
